Problem Statement

- AI-driven learning platform delivers personalized ML education through text, code, audio, and visual explanations. It adapts content to user learning styles, making complex ML concepts easier to understand.

Proposed System

- Uses Generative AI for dynamic concept explanations
- Generates real-time code examples for better understanding
- Adapts content difficulty based on user performance
- Provides multi-modal learning (text, code, visual,audioexplanations)
- Bridges the gap between theory and practical implementation

Technologies and Tools

Backend:

- Flask
- Python
- Gemini, AI APIs

Frontend:

- HTML, CSS, JavaScript

Implementation

Support Vector Machines (SVMs) are powerful supervised machine learning models used for classification and regression tasks. They are particularly well-suited for classification of complex but small-to-medium sized datasets.
The core idea behind SVMs is to find an optimal hyperplane that best separates different classes in the feature space. For linearly separable data, the SVM finds the hyperplane with the largest margin between the closest data points of different classes. These closest data points are called "support vectors."
When data isn't linearly separable, SVMs use a "kernel trick" to map the data into a higher-dimensional space where it might become linearly separable.
Key Concepts of SVMs:
1. **Hyperplane:** A decision boundary that separates data points of different classes. In a 2D space, it's a line; in 3D, it's a plane; and in higher dimensions, it's a hyperplane.
2. **Margin:** The distance between the hyperplane and the nearest data point from either class (the support vectors). SVM aims to maximize this margin. A larger margin generally means better generalization.
3. **Support Vectors:** The data points that lie closest to the hyperplane. They are critical in defining the hyperplane and the margin. If you remove them, the hyperplane might change.
4. **Kernel Trick:** A technique that allows SVMs to implicitly map data into a higher-dimensional feature space without explicitly calculating the coordinates in that space. This allows SVMs to find non-linear decision

This example will cover:

1. **Synthetic Data Generation:** To easily visualize the decision boundary.
2. **Data Preprocessing:** Scaling features, which is crucial for SVMs.
3. **Model Training:** Using `SVC` (Support Vector Classifier).
4. **Model Evaluation:** Metrics like accuracy, confusion matrix, and classification report.
5. **Hyperparameter Tuning:** Using `GridSearchCV` to find optimal `C` and `gamma` values.
6. **Visualization:** Plotting the decision boundary.

```python
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import seaborn as sns

from sklearn.svm import SVC
from sklearn.model_selection import train_test_split, GridSearchCV
from sklearn.preprocessing import StandardScaler
from sklearn.metrics import classification_report, accuracy_score, confusion_matrix
from sklearn.datasets import make_classification, load_iris

# Set a random seed for reproducibility
np.random.seed(42)

# --- 1. Synthetic Data Generation for Visualization ---
```
